

Colour Metafield Demo Script

Showing the client that Shopify's own **Color** field now drives Shop by Colour — the products file themselves into the palette, with no tagging at all.

This demo needs the new code on a theme first. The change is written and pushed to git, but it is not on your store. Section 1 puts it on an **unpublished** preview theme — the live site is never touched.

What the client is going to see

Shopify already stores a **Color** on most products, under **Category metafields** on the product page. Until now Shop by Colour ignored it and guessed from the product's name. It no longer guesses.

COPPER SWATCH	COUNT	WHY
On the live site today	4	Only products with "copper" in their name, plus one sold in a Copper variant
On the preview theme, before you touch anything	6	Mughal Serving Platter and Royal Mandi Platter join — their Color field already said Copper
After the live edit in shot 3	7	Arabic Mandi Platter joins, because you set its Color in front of the client

The line the whole demo exists to land

"You were already telling Shopify what colour each product is. The site just wasn't listening. Now it does — and the two platters that appeared did so on their own, with nobody tagging anything."

1. Prep — put the code on a preview theme

Ten minutes, off camera. Nothing here changes the live storefront.

1 Pull the branch: `git checkout shop-by-colour-metafield`

2 Push it to a brand-new **unpublished** theme:

```
shopify theme push --unpublished --theme "Colour metafield preview"
```

3 The CLI prints a **preview URL**. That is your storefront tab for this demo.

4 Open it, go to **Shop by Colour**, click **Copper**. You should count **6**, including *Mughal Serving Platter* and *Royal Mandi Platter*.

5 Open the live site in another tab and click Copper there: **4**. Keep both tabs — the contrast is shot 1.

Push the section file only. The repo's `templates/index.json` is behind the live theme's settings — the first swatch is "Whimsy Yellow" in the repo and "Yellow" on the live site. A full push would revert theme-editor changes. If `theme push` offers a file selection, restrict it to `sections/hp-shop-by-color.liquid`; otherwise pull the live settings first with `shopify theme pull --only templates/index.json`.

If the two platters do not appear on the preview, stop and tell me before the client session. Both are verified to carry Copper in their Color metafield today, so if they are missing, the metafield is not being read and the rest of the demo will not work either.

Pre-flight checklist

- ☐ Preview theme pushed, preview URL saved
- ☐ Copper reads **6** on the preview and **4** on the live site
- ☐ Arabic Mandi Platter's Color field checked: it says **Silver**, not Copper
- ☐ Two tabs only — admin and preview — everything else closed
- ☐ Full run-through done once, then the Copper entry removed again

2. The demo — about 6 minutes

Shot 1 — the site was guessing

~90 SECONDS · BOTH STOREFRONT TABS

- 1 On the **live** tab, open Shop by Colour → **Copper**. Four products.
- 2 Point out what they have in common: every one has the word *copper* in its name, or is sold in a Copper variant.
- 3 Switch to the **preview** tab, same swatch. Six products.
- 4 Point at the two newcomers: **Mughal Serving Platter** and **Royal Mandi Platter**.

SAY

"Neither of these has 'copper' anywhere in its name — so the old site had no way of knowing, and left them out of the palette. Nobody tagged them just now. Their Color field in Shopify already said Copper; the site simply started reading it."

Both platters are currently out of stock, so they carry a Sold out badge. Get in front of it — "those two are between deliveries" — rather than letting the client spot it and ask.

Shot 2 — where the colour lives

~60 SECONDS · ADMIN TAB

- 1 Open **Products** → **Arabic Mandi Platter**.
- 2 Scroll to **Category metafields**. The category reads *Serving Platters*.
- 3 Rest on the **Color** row. It currently says **Silver**.

SAY

"This is the field, and it's Shopify's own — not something we invented. It's already on every product, under the product category. Right now this platter says Silver."

Shot 3 — add a colour, live

~90 SECONDS · ADMIN, THEN PREVIEW

- 1 Click the **Color** field. Type **Copper** and pick the existing **Copper** entry from the list.

- 2 Leave **Silver** in place — two colours on one product is the point.
- 3 Click **Save** and wait for the confirmation.
- 4 Switch to the preview tab, hard-refresh (**Cmd+Shift+R**), click **Copper**.
- 5 Seven products. Rest the cursor on the **Arabic Mandi Platter** card.
- 6 Click **Silver**. It is there too — same product, both palettes, one entry each.

SAY

"One field, two colours, and it now appears under both — no tags, no duplicate listings, no developer. And because this is Shopify's own colour field, it's the same field that feeds search, filters and the sales channels."

Shot 4 — the products you never have to touch

~60 SECONDS · OPTIONAL

Only if the client asks about products sold in many colours.

- 1 Still on the preview, click **Copper**, then **Silver**. **Persian Metal Handi** is in both.
- 2 Open it in the admin: it has a **Color** variant option with Copper and Silver.

SAY

"This one sells in two finishes from a single listing, so it already appears under both — each showing its own photo. Products like this need nothing at all: the variants do the work."

3. Questions to expect

QUESTION	ANSWER
"So do we still need colour tags?"	No. The tag still works and still wins, but the metafield does the same job. Use whichever is already filled in; do not do both.
"What if the colour name isn't in the list?"	You can add your own entry — several already exist in this store: Burnt Maple, Lunar Ash, Reactive Cloud Grey, Santorini Blue, Riviera Blue, Blush Peach, Honey Mustard, Earthen Rose, Mist Green.
"What if Shopify's name differs from our palette name?"	Nothing gets renamed. Add Shopify's wording to that swatch's Aliases field in the theme editor and both names match from then on.
"How fast is it?"	Immediately — it is read live off the product on every page load.
"Can a product be in several colours?"	Yes, as many as its Color field lists. You just saw one in two.
"Will this put things in the wrong colour?"	Be straight — see the box below. It can, where the Color field lists accents as well as the main colour.

Do not oversell this. The Color field often lists accent colours and patterns, not only the main colour, so a few products land in more swatches than you would choose by hand. Two in the first fifty checked: **Ivory White Platter** shows under Black, and the **3D Teal Matte Spiral Plate** shows under Sage Green. If the client raises it, the honest answer is that the theme can be set to read only the first colour listed — the primary one — which removes both without losing the two platters from shot 1. Offer it as a decision for them, not a defect.

4. After the demo

- ☐ Remove **Copper** from Arabic Mandi Platter's Color field — or keep it, since it is a correct value for that product
- ☐ Decide with the client: all listed colours, or first colour only
- ☐ Delete the preview theme, or keep it until the change is approved for the live site
- ☐ Merge `shop-by-colour-metafield` once approved, then publish
